Exp No:- 8 Date:-

Aim:-
The aim of the Exercise is to understand & implement shell using TCP sockets. This will demonstrate how a client can connect back to an attacker machine and allow the attacker to remotely execute commands on the client machine.

Tools of Technologies:-

- Programming Languages : Python 3.x
- libraries
- Socket for network communication via TCP/IP sockets

LAB Setup:-

1. Server Machine
   Ip Address : the machine that will be listening for incoming connection from the client

Procedure:-
Step 1:- Set up the server scripts on the Attackers machine!
create a new python script on the attacker machine.

2. copy the following code into the script
(import socket import subprocess import os

OS
Server_IP = 0.0.0.0
Server_Port = 9999
Socket.SOCK_STREAM.

3. Run the server script : open a terminal and RUN:

Python 3 Server.py.

the screen will now listen for connections on 0.0.0.0 & port 9999

4) Observe the op on the attached terminal. Each command will be executed normally on the client machine and the result will be displayed on the server.

O/P:

1. Server side output.

the server successfully listens on the specified port and waits for an incoming connection from the client.

shell > pwd / home / user

shell > cd / home

shell > ls user

another - user

shell > exit

[*] closing connection.

Result :-
The client successfully connected to the server and executed commands by the attacker, returning their output.
